this book offers an accessible introduction to the topic of impact evaluation and its practice in development while the book is geared principally towards development practitioners and policymakers designing prospective impact evaluations we trust that it will be a valuable resource for students and others interested in using impact evaluation prospective impact evaluations should be used selectively to assess whether or not a program has achieved its intended results or to test alternatives for achieving those results we consider that more and better impact evaluation will help strengthen the evidence base for development policies and programs around the world if governments and development practitioners can make policy decisions based on evidence including evidence generated through impact evaluation our hope is that development resources will be spent more effectively and ultimately have a greater impact on reducing poverty and improving people s lives the three chapters in this handbook provide a non technical introduction to impact evaluations including why evaluate in chapter 1 how to evaluate in chapter 2 and how to implement impact evaluations in chapter 3 these elements are the basic tools needed in order to successfully carry out an impact evaluation from a methodological standpoint our approach to impact evaluation is largely pragmatic we think that the most appropriate methods should be identified to fit the operational context and not the other way around this is best achieved at the outset of the program through the design of prospective impact evaluation that can be built into the project s implementation we argue that gaining consensus between key stakeholders and identifying an evaluation design that fits the political

and operational context is as important as the method itself we also believe strongly that impact evaluations should be upfront about their limitations and caveats finally we strongly encourage policymakers and program managers to consider impact evaluations in a logical framework that clearly sets out the causal pathways by which the program works to produce outputs and influence final outcomes and to combine impact evaluations with monitoring and selected complementary evaluation approach to gain a full picture of performance this book builds on a core set of teaching materials developed for the turning promises to evidence workshops organized by the office of the chief economist for human development hdnce in partnership with regional units and the development economics research group decrg at the world bank

cd rom water availability is one of the main limiting factors that control ecosystem functions and productivity in semiarid regions vegetation of these regions usually presents a patchy distribution where sparse plant cover is interspersed over a bare soil during the few rainfall events runoff is generated in non vegetated areas and redistributed towards vegetation which act as surface obstruction for water sediments and nutrients thus non vegetated areas are more susceptible to water erosion processes non vegetated areas from semiarid ecosystems around the world are often covered by biological soil crusts bscs bscs result from an intimate association between soil particles and cyanobacteria algae microfungi lichens and bryophytes these communities live within or immediately on top of the uppermost millimeters of soil influencing soil surface properties involved in infiltration runoff generation and water erosion several papers have demonstrated that bscs are one of the most important soil stabilizing factors in drylands there are however contradictory results on the role that bscs play in regulating soil water fluxes some studies point bscs as runoff sources that may increase downslope erosion or on the contrary may represent an additional supply of water for downslope vegetation allowing its survival the impact of this additional runoff should be evaluated at less detailed scales than the patch and to analyze all interactions in terms of water sediments and nutrients between areas covered by bscs and vegetated patches in order to establish the real effects of bscs on both runoff and erosion also to correctly predict the impact of future climate changes or antropic disturbances on hydrological behavior and water erosion in systems dominated by bscs their effects should be included on spatially distributed runoff and erosion models until now the influence of bscs on these processes has been addressed almost exclusively at patch scale despite the fact some authors have pointed the need of upscaling their effects and even more their influence on runoff generation and water erosion was never considered in spatially implicit medelling the goal of this thesis is to

determine bsc effects on runoff and water erosion from plot to catchment scale in a typical semiarid ecosystem to achieve this objective first direct and indirect effects of bscs at patch scale must be clearly defined under natural rainfall conditions to solve the controversy about bscs effects on runoff generation to know the direct and indirect relationships among soil surface characteristics bsc cover and type topography rainfall characteristics duration amount and intensity and runoff structural equation models sem were applied our results reveal the critical importance of bscs on runoff and water erosion both processes in biologically crusted areas are directly controlled by crust type and cover bscs also modified some soil surface properties involved in runoff generation and water erosion such as microtopography surface stability or water repellency the final interaction of both direct and indirect bscs effects determine the hydrological behavior of these surfaces under natural rainfall conditions moreover the final effect of bscs on runoff generation is strongly driven by rainfall properties which determined the set of complex interactions among bscs type and developmental stage and soil surface properties on one hand during low intensity rains bsc induced microtopography increases the amount of surface micro depressions which act as temporal water sinks reducing the connectivity among source areas delaying runoff initiation and reducing runoff rates on the other hand during intense rainfall events bscs type and water repellency are the main factors determining runoff generation when the effects of bscs are analyzed at coarser scales including all interactions among bscs and vegetated areas on a whole catchment our results reveal the importance of the interactions between areas with bscs and areas with vegetation on runoff generation and water erosion we show the capacity of vegetated areas to retain runoff waters generated by upslope biologically crusted areas as an important driver for the hydrological and erosional response at catchment scale however the capability of vegetated areas to trap and retain water and sediments is limited and can be exceeded during high magnitude events increasing catchment connectivity as well as runoff and water erosion at the catchment outlet even during high magnitude events when the runoff generated in bsc areas reaches the channel network the local protection provided by bscs also affects downslope areas and the catchment response these results confirm that bscs must be included in runoff and soil erosion models to obtain reliable predictions of the spatial pattern of runoff and water erosion in catchments with abundant bscs in order to correctly introduce the effects of bscs in these models it is necessary to have an accurate spatial characterization of bscs it is shown that a spectral mixture analysis is required for the precise characterization of the complex spatial distribution of bscs due to the intrinsic spatial heterogeneity of semiarid ecosystems and to the spectral similarities among bscs dry vegetation and bare soil due to the methodological and practical application problems of spectral mixture analysis when it is applied to spectrally complex areas or when some surface elements only appear in specific areas of the image we needed to develop a novel methodology for bscs classification and quantification lichen and cyanobacteria dominated cbs based on hyperspectral images support vector machine classification was applied for spectral and ecological classification of homogenous areas to solve the mentioned problems inherent to spatial heterogeneity immediately afterwards spectral mixture analysis sma was applied to each svm class to quantify the proportion of each type of surface cover within each pixel relative abundance images obtained with this methodology achieve a relatively high accuracy for different types of bscs and have demonstrated to be an adequate source of spatially distributed information to correctly characterize surface properties in biologically crusted drylands systems moreover to have the spatial distribution of type and abundance of bscs allows to increase the accuracy of modeled runoff and erosion thus when bscs effects are not included in the lisem model an important increase in modeled water erosion was observed in areas where bscs was not considered
